**Abstract**

**Objectives:** A clinical trial was carried out to investigate the effect of Anchovy of *Stelophorus commersonii* on mutans streptococci inhibiting the growth of the salivary mutans streptococci for a period one week consumption. **Methods:** Before enrolled in the study, respondents fill and signature the informed consent. Twenty respondents participated as the subjects on the clinical trial, conducting two times of treatment as follows: twenty as treatment groups before and after consuming anchovy of *Stelophorus commersonii* and the twenty subjects as control groups before and after consuming non-anchovy of *Stelophorus commersonii*. Saliva samples were collected before and after consuming anchovy of *Stelophorus commersonii* and with a non-anchovy of *Stelophorus commersonii*. A serial dilution was made, followed by inoculating on TYS20B medium (Shaeken, M.J.M, et al, 1986). Data which were obtained from colony forming units of salivary mutans streptococci grew on the TYS20B medium before and after consuming anchovy of *Stelophorus commersonii* were analyzed in a descriptive and t test. **Results:** showed that there is no significance in the average amount of *Streptococcus mutans* colonies between before and after consuming non-anchovy of *Stelophorus commersonii*. However, a significant difference was found respectively as results before and after consuming anchovy of *Stelophorus commersonii*. **Conclusion:** We concluded that Anchovy fish of *Stelophorus commersonii*, caries can be prevented

Key words: Anchovy of *Stelophorus commersonii* - Salivary Mutans Streptococci.

**Introduction**

*Streptococcus mutans* harbored in the dental plaque is thought to be the main agent to caries prevalence. Acidogenicity and aciduricity are important biochemical characteristics for cariogenicity of microorganisms. The mutans streptococci have both of these properties and considered the most cariogenic group within the oral micro flora.¹ ²

For this reason, early prevention is needed to maintain the oral health by rinsing through using mouthwash and tooth brushing. It is the most widely used and socially accepted form of oral hygiene.³ Mouth rinsing and tooth brushing are the principal way for mechanical removal of plaque and to prevent *Streptococcus mutans* colonized in teeth.³ ⁴
Anchovy fish of *Stelophorus commersonii*, contains nutritional contents of carbohydrates, proteins, fats, vitamins and minerals. One of the important nutritional elements in Anchovy fish is the fluoride. The fluoride level in this fish is quite high ranging from 5 to 35 ppm, thereby anticipating that oral health is maintained by regularly consuming Anchovy fish.

This research is expected to contribute significantly to the world of science that Anchovy substrate of *Stelophorus commersonii* can inhibit the bacterial growth of mutans of *Streptococci mutans*, therefore in a long term of consuming Anchovy fish of *Stelophorus commersonii*, caries can be prevented.

Materials and Methods

The research is done by using Quasi experimental laboratory method in human with epidemiological approach. The bacteria used as analysis unit were local strains of mutans of *Streptococcus mutans* isolated from human harbouring species in Panggang Island Indonesia.

Twenty subjects participated conducting two times treatment as treated group and being also as control group. The subjects participated in this study, all were good and oral health, no evidence of progressive periodontal diseases and no untreated caries.

The analyzed unit was mutans of *Streptococci mutans* in saliva. Mutans of *Streptococcus mutans* are cultivated in Tryptose - Yeast Sucrose with Bacitracin (TYS20B). Brain Heart Infusion Broth(BHI) was performed. Those specimen are incubated in anaerobic jar at 37°C Celsius degree for 3 X 24 hours.

Respondents are examined their oral hygiene, their oral hygiene shall be on average. Respondents fill and signature the informed consent.

Before and after consuming non-anchovy of *Stelophorus commersonii* and anchovy of *Stelophorus commersonii*. Respondents chew sterile paraffin to obtain considerable amount of saliva and the saliva is collected. Two hours after consuming anchovy, saliva are collected.

Saliva samples, then make a serial dilution. 1 ml of saliva is diluted with 9 ml sterile saline to make a serial dilution and from the tube of 1000 fold dilution, is then take 0.1 ml of solution to inoculate in the selective medium of TYS20B (Schaken et al, 1986).

All samples are incubated in anaerobic jar at temperature of 37°C Celsius degree for 3 X 24 hours..

Subjects were treated with consuming anchovy of *Stolephorus commersonii* and non-anchovy of *Stolephorus commersonii*, 3 X 50 gram anchovy daily for a period of one week consumption.

The Colony Forming Units (CFU) of *Streptococcus mutans* which grew in the TYS20B medium are then counted and recorded.

Data which were obtained from colony forming units of salivary mutans streptococci grew in TYS20B medium before and after treatment were analyzed in a descriptive and “t” test.
Results

The results of analyzed colony forming units (CFU) amount of *Streptococcus mutans* which grew on TYS20B media before and after consuming with anchovy and non-anchovy of *Stolephorus commersonii* are shown in table 1.

Table 1. Mean and Standard Deviation (SD) of CFU *Streptococcus mutans* on treatment with anchovy and non-anchovy of *Stolephorus commersonii*

<table>
<thead>
<tr>
<th></th>
<th>N=20</th>
<th>Mean</th>
<th>SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before - non anchovy</td>
<td>410.50</td>
<td>234.90</td>
<td></td>
</tr>
<tr>
<td>After - non anchovy</td>
<td>387.00</td>
<td>326.12</td>
<td></td>
</tr>
<tr>
<td>Before - anchovy</td>
<td>381.75</td>
<td>315.91</td>
<td></td>
</tr>
<tr>
<td>After - anchovy</td>
<td>84.25</td>
<td>80.08</td>
<td></td>
</tr>
</tbody>
</table>

Table 1 shows that CFU of *S. mutans* after consuming with anchovy of *Stolephorus commersonii* ($X=84.25 \pm SD=80.08$) is lower than before consuming with anchovy of *Stolephorus commersonii* ($X=381.75 \pm SD=315.91$). The CFU of *S. mutans* after consuming with anchovy of *Stolephorus commersonii* ($X=84.25 \pm SD=80.08$) is also lower than after consuming with non–anchovy of *Stolephorus commersonii* ($X=387.00 \pm SD=326.12$).

The significance of the effectiveness of anchovy of *Stolephorus commersonii*, a “t” test analysis was done and the results can be seen in table 2. Significant level was accepted when p–level at 5 % was lower than 0.05($p<0.05$).

Table 2. “t” test on treatment with xylitol chewing gum and non-xylitol

<table>
<thead>

<th>Df</th>
<th>t</th>
<th>p</th>
<th>Significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before-After Consuming (non-anchovy)</td>
<td>18</td>
<td>0.285</td>
<td>0.946</td>
<td>$p&lt;0.05$</td>
</tr>
<tr>
<td>Before-After Consuming (anchovy)</td>
<td>18</td>
<td>3.560</td>
<td>0.005</td>
<td>$p&lt;0.05$</td>
</tr>
<tr>
<td>Before chewing (non-xylitol – xylitol)</td>
<td>18</td>
<td>0.440</td>
<td>0.800</td>
<td>$p&lt;0.05$</td>
</tr>
<tr>
<td>After chewing (non-xylitol – xylitol)</td>
<td>18</td>
<td>2.780</td>
<td>0.010</td>
<td>$p&lt;0.05$</td>
</tr>
</tbody>
</table>

No significant difference was found between the CFU of *S. mutans* before and after consuming with non-anchovy of *Stolephorus commersonii*, where p-level at 5% was 0.946 and t-value was 0.295.

As expected the amount of CFU salivary mutans streptococci showed very significant difference the CFU of *S. mutans* before and after consuming with anchovy of *Stolephorus commersonii*, where p-level at 5% was 3.560 and t-value was 0.005. When CFU of *S. mutans* before and after consuming with non-anchovy of *Stolephorus commersonii* compare to before consuming with anchovy of *Stolephorus commersonii* the t-value 0.440 where p-level at 5% was 0.800 meaning that there is no significant difference.
After consuming with non–anchovy of *Stolephorus commersonii* compared to after consuming with anchovy of *Stolephorus commersonii* also showed significant difference (t-value was 2.780 where p-level at 5% was 0.010)

**Discussion**

The results in table 1 had shown that the amount of CFU of *Streptococcus mutans* after consuming with anchovy of *Stolephorus commersonii* lower than the amount of CFU of *Streptococcus mutans* after consuming with non–anchovy of *Stolephorus commersonii*.

After consuming non-anchovy of *Stolephorus commersonii* the CFU of *Streptococcus mutans* decreased comparing with the CFU of *Streptococcus mutans* before consuming with non-anchovy of *Stolephorus commersonii*.

The results from table 2 showed that where was highly significance difference in the average amount of *Streptococcus mutans* colonies between before and after consuming with anchovy of *Stolephorus commersonii*.

In the past study it had been proven that Anchovy substrate of *Stelophorus commersonii* has anti microbial activity against standard strains of *Streptococcus mutans LM 7*, *Streptococcus mutans JC 2*, *Streptococcus mutans KPSK2*, *Streptococcus mutans Ing Britt* and *Streptococcus sobrinus B13* and local strains of mutans of *Streptococcus mutans* isolated from human harbouring species*.

In Indonesia, dental caries is still a big problem in the dentistry, although efforts to overcome it have been made, such as by using fluoridation method, which can be systemic and topical application.

However considering the very small need of systemic fluoride by human beings, i.e about 1.7–3.3 ppm daily, it is very difficult to determine the concentration of ionic fluoride which should be given to the people, because of the harmful side effect of systemic fluoride administration, so this method is already left out.

So we carried out another method of topical fluoridation among others by chewing food, before it swallowed, which is rich in fluoride, i.e anchovy *Stelophorus commersonii*, that has fluoride property about 5 – 35 ppm.

**Conclusion**

The research showed that commersons anchovy has bactericide activity on mutans of *Streptococcus mutans*. Commersons anchovy of *Stelophorus commersonii* is traditional food for the population along the coast of Indonesia.

Because Commersons anchovy contains high fluoride ion, it also can be used as a topical application, so early risk of caries can be anticipated, by in a long term of consuming Anchovy fish of *Stelophorus . commersonii*, caries can be prevented.
