Mucocele is a common benign lesion in the oral cavity. A mucocele is a swelling in mouth caused by a blocked salivary gland. Mucoceles are painless but can be bothersome for patients to eating and speaking. Most mucoceles are visually identified. Only a few of mucoceles goes away without any special treatment, but most of mucoceles are removed by surgical process. The most common location of the extravasation mucocele is the lower lip, while retention mucoceles can be found at any other site. Mucoceles Can affect the general population, but most commonly young patients. Trauma is the main etiologic factor involved in the development of mucoceles in children. The proper treatment can remove mucoceles without side effects. It is essential for a dentist to visually recognize oral lesions such as mucocele and for the proper treatment. This paper reports a case of mucocele in child has been threatment by surgical removal and the result is no recurrence.

Keywords: mucocele, surgical, child

Introduction

A mucocele is a swelling in mouth, also known as “mucous cyst of the oral mucosa”. Although mucocele is benign, it can affect the oral functions such as chewing and speaking and oral hygiene. Mucoceles can have very similar features with other oral lesions. Thus, a dentist must inform patients on their oral lesions advise them to seek further diagnosis and treatment in order to prevent any potential medical threats (1).

Etiology of Mucocele can happen when a salivary gland is injured or blocked. Many salivary glands exist in mouth, secreting saliva. Saliva is made of water, mucus and enzymes. Saliva moves from a gland into mouth through tiny tubes called ducts. Sometimes, one of these ducts can be cut, the saliva pools at the cut spot, and causes a swelling, or a mucocele. Mucoceles occur on the tongue, inside the cheeks, the roof of the mouth, the floor of the mouth, or around tongue or lip piercings. Most mucoceles are painless but can be bother some because patients are sensitive to the bumps in their mouth. Mucoceles can get in the way of eating or speaking and are prone to biting. Shallow mucoceles may burst and release straw-colored fluid. Deeper ones can last longer and are more likely to bother patients. Mucoceles are benign. However, if they are left untreated, they can organize and form a permanent bump on the oral surface. Mucoceles occur where salivary glands exist. The dentist should look for a rubbery, bubble-like swelling. Mucoceles are usually found inside the lower lip, but they can also be found on the inner side of the cheek, the anterior ventral tongue, the roof of the mouth, the floor of the mouth, and rarely the upper lip (3,4).
Mucoceles semitransparent and tough and their size range from a few millimeters to centimeters. Superficial mucoceles have bluish color while mucoceles in a deeper lesion have the mucosa color. A dentist should ask if a patient has experienced trauma in that area. The patient might have bitten the lip or was hit in the face with something. Also, some medicines can thicken saliva, and it can plug up a salivary gland and cause a mucocele. Mucoceles do not change color when pressure is applied on them. If a patient has a blue swelling that looks like a mucocele, the dentist may put pressure on it to see if it changes color. If it does, it may be a harmless growth made of blood vessels. This is known as a hemangioma. The dentist may take out the swollen tissue and send it to a laboratory. The laboratory can tell if the tissue is a mucocele, or if it is some other form of oral lesion. The patient may get an X-ray of the area, and the X-ray will show if the patient has a salivary gland stone. X-rays are often done for patients who have ranulas (3,5).

With proper diagnosis and treatment, mucoceles can be cured with an excellent outcome. Trauma is a leading cause mucocele. A patient should avoid piercing in mouth piercing and try not to bite his/her lip (3).

Infrequently, a mucocele goes away without treatment. But if some mucoceles remain untreated, they can scar over. The dentist should examine any swelling in patients’ mouth. Mucoceles are usually removed by surgery. The dentist may use a scalpel or a laser to remove a mucocele. The removed mucocele tissue will be sent to a laboratory for further evaluation. There is a chance that another mucocele develops after the one is removed. Doctors also can use corticosteroid injections before attempting a surgical treatment. These injections sometimes bring down the swelling, and then the patient may not need surgery.

A few cases of mucoceles and ranulas resolve naturally. Without treatment, especially in infants and young children. As an alternative to surgery, lesion aspiration and follow-up for about 6 months have been suggested if symptoms are minimal in infants and young children (1,4,6).

The main dental implication of mucoceles would be tissue trauma to the buccal mucosa or the lip region because of the swollen tissue and tendency for the patient to bite the lesion while chewing. The dentist should inform the prevention of mucoceles to patients who has tendency of biting mouth tissues.

**Case Report**

A girl 5 years old reported to go to “The Dental Speciality Clinic” with the chief complaint of a big swelling on the right side of the lower lip since two months. The swelling was diagnosed as an extravasation mucocele after history and clinical examination. The treatment involved surgical resection of the tissue. The mucocele was removed under infiltrating local anesthesia (2% lidocaine with epinephrine 1:100.000; one cartridge). The child was sit in the dental chair. Its histopathological examination & regular follow up to check for uneventful healing.

After one week regular recall and checkup for the reoccurrence of the lesion was done. No recurrence was observed.

**Discussion**

The incidence of mucoceles in the general population is 0.4-0.8%, with scant differences between males and females (7). Our own series coincides with this, since 55% of the lesions were found in males (Figure 1). As regards patient age, different authors report the peak incidence to be in the second or third decades of life (8). An interesting and controversial aspect of mucoceles is their origin. Bhaskar et al. suggested obstruction of the salivary gland ducts as the cause of mucoceles, though this hypothesis has lost support in favor of a traumatic origin of the lesions (9,10). The literature contains a number of studies that confirm the traumatic etiology of these lesions. In our series we identified an antecedent of trauma or of nibbling in 34% of the patients - this figure being low in comparison to the percentages

reported in other studies. In any case, the typical location of these lesions in the lower lip (more susceptible to accidental trauma or nibbling and suction habits), their presence in young patients, and the exceptional presence of calculi in the minor salivary glands, all support this etiopathogenic theory (Figure 2). As regards mucocele location in the oral cavity, most investigators consider the lower lip to be the most frequently affected location (40-80% of all cases), followed by the cheek mucosa and floor of the mouth. The tongue, palate, and upper lip are infrequent locations. The present study coincides with these observations, since 73.5% of the lesions were in the lower lip, with very little involvement of other locations. In addition, the lower lip mucocles were predominantly located on one side with very few medial lower lip locations. These data would be directly related to the greater capacity of certain teeth to exert trauma upon the lip, as a result of their spatial distribution. In this sense, there also have been reports of mucocles produced as a result of the action of dental braces. In the present study mucocele growth was generally seen to be slow. According to Harrison, the lesions develop over a period of one week to five years, though the most common duration is three weeks to three months (8).

Mucoceles may be located either as a fluid filled vesicle or blister in the superficial mucosa or as a fluctuant nodule deep within the connective tissue. Spontaneous drainage of the inspissated mucin especially in superficial lesions followed by subsequent recurrence may occur. The surface of long standing lesions may show fibrosis (2).

The development of Mucoceles usually depends on the disruption of the flow of saliva from the secretory apparatus of the salivary glands. The lesions are most often associated with mucus extravasation into the adjacent soft tissues caused by a traumatic ductal insult, which may include a crush-type injury and severance of the excretory duct of the minor salivary gland. Conventional treatment is commonly surgical extirpation of the surrounding mucosa and glandular tissue down to the muscle layer. With a simple incision of the mucocele the content would drain out but the lesion would reappear as soon as the wound heals (11).

There is no need for treatment if superficial extravasation mucocles resolve spontaneously. Small mucocles can be removed completely with the marginal glandular tissue before suturing. In the case of larger mucocles, marsupialization would avoid damage to vital structures. Clinically there is no difference between both types of mucocele, and are therefore treated in the same manner (12).

Conclusion

Mucoceles can develop from any population. Although mucocles are painless and intransmissible, they can affect regular eating and speaking routine of patients. Thus they should be treated properly and prevented if possible. The dentist should help patients prevent mucocles by diagnosis and education and advise them to receive the proper treatment for their oral health and comfort.

Mucoceles of the oral cavity are more common in young males. Traumatisms are the usual cause and the most frequent location is the mucosa of the lower lip.

The treatment of lesions such as mucocele must be planned taking into consideration the various clinical parameters and any oral habits that are probable as these lesions have a propensity of recurrence. Prevention for mucocele, a patient should try not to bite his/her lip and preventive from traumatic injury.
