**ABSTRACT**

**Background:** Synthetic bone graft is a material that resembles human bone phase and is developed due to clinical demand. Calcium carbonate ( $\text{CaCO}_3$ /Calcite) has been used as bone substitution one of the methods to fabricate calcite is phase transformation by dissolution-precipitation reaction. Previous study did the same method but with lower temperature ( $<100^\circ\text{C}$ ). Calcium sulfate anhydrate ( $\text{CaSO}_4$ ) granules used as precursor is immersed in 0.5 mol/L sodium carbonate ( $\text{Na}_2\text{CO}_3$ ) solution at  $100^\circ\text{C}$  for 12 h. **Objective:** This study aims to fabricate  $\text{CaCO}_3$  granules from  $\text{CaSO}_4$  granules when the temperature is higher than the previous study. **Methods:** Fabricate  $\text{CaCO}_3$  granules using  $\text{CaSO}_4$  granules as precursor by dissolution-precipitation reaction in  $\text{Na}_2\text{CO}_3$  solution with 12 h immersion time with  $100^\circ\text{C}$  temperature. Powder X-ray diffraction patterns and Fourier transform infrared spectra study will be performed to characterize the granules. **Results:**  $\text{CaCO}_3$  granules are fabricated by dissolution-precipitation reaction in  $\text{Na}_2\text{CO}_3$  solution with 12 h immersion time when the temperature was  $100^\circ\text{C}$ . **Conclusion:**  $\text{CaSO}_4$  granules used as precursor are a potential material to fabricate  $\text{CaCO}_3$  by using dissolution-precipitation reaction with 12 hours immersion time and  $100^\circ\text{C}$  temperature.

**Keywords:** Bone graft, phase transformation, dissolution-precipitation reaction, calcium sulfate anhydrate, calcium carbonate.

**INTRODUCTION**

Bone grafts are used for augmentation or stimulating new bone formation in the case of bone defects. Autograft is a bone graft originating from the patient itself, so it becomes the gold standard in bone grafting due to excellent osteoconductive and osteoinductive properties.<sup>1</sup> Due to limited availability of the bone part that can be taken and high clinical demand, a synthetic bone graft was developed. Synthetic bone graft must have characteristics similar to bones<sup>2-4</sup>, one of which is calcium carbonate. Marine coral has been used as bone graft ( $\text{CaCO}_3$ ).<sup>5</sup> Calcium carbonate has three polymorphs: vaterite, aragonite, and calcite. Among the three polymorphs, vaterite is the most unstable, and calcite is the most stable.<sup>5-7</sup> Aragonite has been extensively studied since coral can be used as a bone filling material. Coral

can affect nature, and produce impurities when used as bone fillers.<sup>5</sup> Therefore, research has been developed on the manufacturing of artificial calcium carbonate. Research that explains artificial calcium carbonate is still limited.

Artificial calcium carbonate has only been used in the form of blocks in the medical field. Blocks have dense structure, so the material resorption is longer than granules. As seen in the research conducted by Ishikawa, et al (2017) with the composition transformation method through precipitation dissolution reaction, which used  $\text{CaSO}_4$  blocks as precursor to produce  $\text{CaCO}_3$  blocks. By immersing  $\text{CaSO}_4$  precursor in  $\text{NaHCO}_3$  solution pure  $\text{CaCO}_3$  can be produced in 14 days at  $80^\circ\text{C}$ . The shape of the granule has a high surface area so that phase transformation can occur more quickly, as seen in Ishikawa's research, et al. (2015) making

calcium carbonate granules by immersing  $\text{Ca}(\text{OH})_2$  granules in  $\text{Na}_2\text{CO}_3$  solution,  $\text{CaCO}_3$  granules can be produced within 4 days at a temperature of  $80^\circ\text{C}$ .<sup>8</sup> The use of  $\text{Ca}(\text{OH})_2$  is considered to be unstable at high temperatures, so the stable precursor in high temperature is selected,  $\text{CaSO}_4$ .<sup>5</sup>

The use of  $\text{CaSO}_4$  granules has been done before to make pure  $\text{CO}_3\text{Ap}$  granules by precipitation dissolution reaction within 24 hours at  $100^\circ\text{C}$ , and if the temperature is increased to  $200^\circ\text{C}$  pure  $\text{CO}_3\text{Ap}$  is obtained within 6 hours.<sup>9</sup> Based on the research, it is revealed that the temperature can accelerate precipitation dissolution reactions. Research on the manufacturing of  $\text{CaCO}_3$  that has been done previously used temperature of lower than  $100^\circ\text{C}$ . Based on the previous study, this study uses temperature at  $100^\circ\text{C}$ , we speculate that higher temperature can accelerate phase transformation through dissolution of precipitation on the granule  $\text{CaSO}_4$  to  $\text{CaCO}_3$  by identification the characterization of the granules.

## MATERIALS AND METHODS

This study was adapted from Ishikawa et al. (2017) using precipitation dissolution reaction method, by making precursor of  $\text{CaSO}_4$  blocks which are then crushed to granules and immersed in  $\text{Na}_2\text{CO}_3$  solution, soaking for 12 hours to produce  $\text{CaCO}_3$  granules.

### Calcite granule ( $\text{CaCO}_3$ )

This study used  $\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$  powder (Wako Chemicals, Osaka, Japan).  $\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$  powder was mixed with distilled water with 0.5 ratio. A mixture of paste was poured into a plastic mold with a diameter of 6mm and a height of 3mm. Left to set for 1 hour, then  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  block was produced. The  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  block was then burned in the furnace at  $700^\circ\text{C}$  with an increase of  $5^\circ\text{C} / \text{min}$  and left for 5 hours at  $700^\circ\text{C}$  to form a  $\text{CaSO}_4$  block. The  $\text{CaSO}_4$  block was then crushed using mortar and was sieved using a sieve to obtain granules with a size of  $300\text{--}500\mu\text{m}$ . The  $\text{CaSO}_4$  granules were immersed in a solution  $0,5 \text{ mol/L Na}_2\text{CO}_3$  (Wako Chemicals, Osaka, Japan) at  $100^\circ\text{C}$  for 12 hours, then dried at  $80^\circ\text{C}$ .

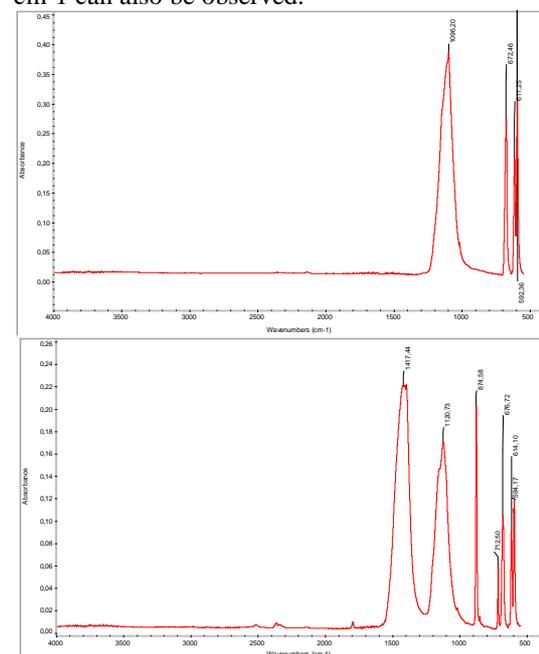

### Characterization of Calcite Granule

The composition of calcite granules was evaluated using Fourier Transform Infra Red (FTIR; thermoscientific, FTIR-ATR, Japan) which was carried out using the ATR method and X-Ray Diffraction (XRD; Xpert PRO, Pananalytical) and was analyzed using 40KV  $\text{CuK}\alpha$  radiation tube voltage and 40 -MA tube

current. The diffraction angle was scanned at  $2\theta$  with a range from  $10^\circ$  to  $40^\circ$  with continuous mode, then the graph was processed using HighScore software (HighScore suite, Malvern Analytical)

## RESULTS

This research produces  $\text{CaCO}_3$  granules made through phase transformation based on precipitation dissolution reactions. As a result of the characterization with FTIR,  $\text{CO}_3$  groups are seen (fig. 1). Figure 1A shows the absorbance of the precursor  $\text{CaSO}_4$  before immersion in a solution of  $\text{Na}_2\text{CO}_3$ . In the figure, the absorbance peaks at the wavelengths of  $1100 \text{ cm}^{-1}$ ,  $672 \text{ cm}^{-1}$ ,  $611 \text{ cm}^{-1}$  and  $592 \text{ cm}^{-1}$ , illustrating the form of sulfate groups ( $\text{SO}_4$ ). The cluster obtained corresponds to the research conducted by Nomura, et.al (2014).<sup>9</sup> Figure 1 (B) shows the FTIR spectrum of  $\text{CaSO}_4$  after immersion in a solution of  $0.5 \text{ mol / L Na}_2\text{CO}_3$  for 12 hours. There is a new absorbance peak at wavelengths of  $1417 \text{ cm}^{-1}$ ,  $875 \text{ cm}^{-1}$  and  $712 \text{ cm}^{-1}$  which indicates the presence of  $\text{CO}_3$ -groups. The three absorbances show the characteristics of calcite. In addition, the absorbance of  $\text{SO}_4$  groups at waves  $1100 \text{ cm}^{-1}$ ,  $594 \text{ cm}^{-1}$ ,  $614 \text{ cm}^{-1}$  and  $676 \text{ cm}^{-1}$  can also be observed.

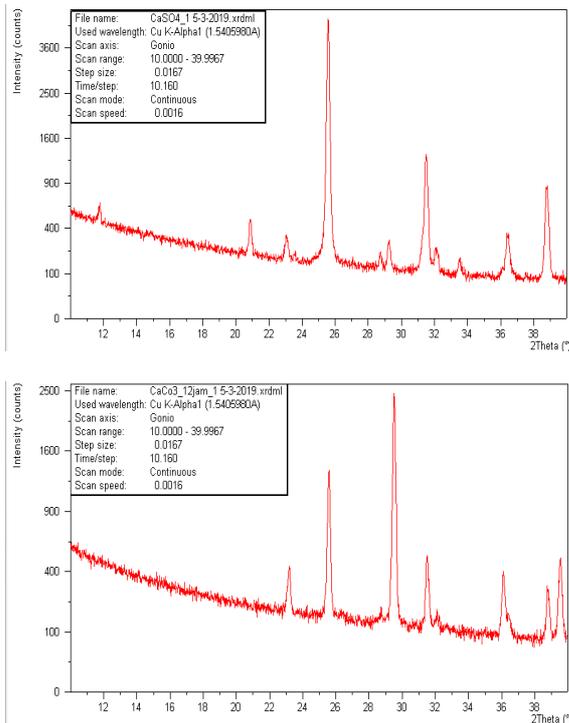

**Figure 1.** (A) FTIR spectrum of  $\text{CaSO}_4$  before immersion. (B) FTIR spectrum of  $\text{CaSO}_4$  after immersion for 12h at  $100^\circ\text{C}$

The results of FTIR spectrum analysis of  $\text{CaSO}_4$  samples before and after immersion in  $0.5 \text{ mol / L Na}_2\text{CO}_3$  for 12 hours that calcite is formed. On the other hand, absorbance which shows  $\text{CaSO}_4$  is also still found after immersion.

This indicates that  $\text{CaSO}_4$  has not been completely converted into calcite under these conditions.

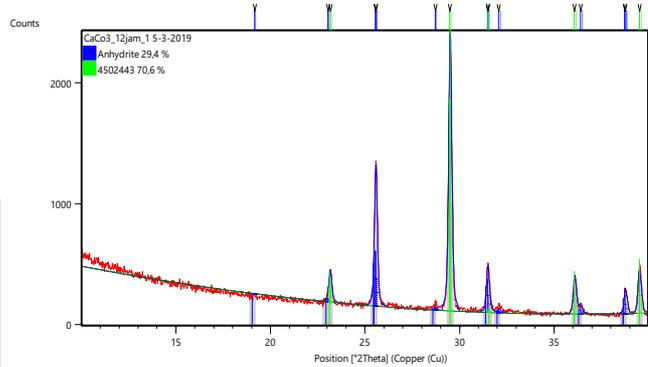

The results of XRD characterization in this study are the same as the research conducted (Ishikawa et al., 2015), namely the existence of the  $\text{CaCO}_3$  phase at  $2\theta$   $30^\circ$ . The results of XRD analysis show that there are 2 phases formed after immersion, namely the phase of  $\text{CaSO}_4$  and  $\text{CaCO}_3$ , evidenced in the diffraction peak at  $26^\circ$  and  $30^\circ$ . Previously Ishikawa et al. (2017) obtained the results of 2 phases of  $\text{CaSO}_4$  and  $\text{CaCO}_3$  but only after soaking for 3 days.

**Figure 2.** (A) XRD diffraction of  $\text{CaSO}_4$  before immersion. (B) XRD diffraction of  $\text{CaSO}_4$  after immersion for 12h at  $100^\circ\text{C}$ .

XRD diffraction pattern (fig. 2, (A)) which is seen from specimens in the form of  $\text{CaSO}_4$  granules obtained from  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  combustion at  $700^\circ\text{C}$  for 5 hours, shows visible peaks that match with ICDD cards which indicate that the sample still has  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  phase (ICDD) database ref. code 96-901-5351) at peak  $12^\circ$  and  $20.8^\circ$  with very low intensity. Phase  $\text{CaSO}_4$  (ICDD database ref. Code 96-500-0041) which is located at a peak of  $23^\circ$ ,  $26^\circ$ ,  $32^\circ$ ,  $36.2^\circ$  and  $38.7^\circ$ . The characteristic peak of  $\text{CaSO}_4$  is  $26^\circ$ , in the picture it appears to be the peak with the highest intensity compared to the other peaks. In figure (B) the XRD diffraction pattern shows that there are 2 phases namely  $\text{CaSO}_4$  and  $\text{CaCO}_3$ , in the  $\text{CaSO}_4$  granule treated with 12 hours immersion in a solution of  $0.5 \text{ mol/L}$

$\text{Na}_2\text{CO}_3$  indicating the existence of  $\text{CaSO}_4$  phase (ICDD database ref. Code 96-500 -0041) which is located at  $23^\circ$ ,  $26^\circ$ ,  $32^\circ$ ,  $36.2^\circ$  and  $38.7^\circ$  also has the phase of  $\text{CaCO}_3$  (ICDD ref. Code 96-450-2444) at  $20^\circ$ ,  $23^\circ$ ,  $30^\circ$ ,  $32^\circ$ ,  $36^\circ$ ,  $39^\circ$ . Diffraction pattern image 2 (B) shows the main characteristic peak of  $\text{CaCO}_3$ , which is at  $30^\circ$ .

**Figure 3.** XRD data match of  $\text{CaSO}_4$  after immersion for 12h with ICDD reference, shown that  $\text{CaSO}_4$  phase (blue) and  $\text{CaCO}_3$  (green).

## DISCUSSIONS

Phase transformations based on precipitation dissolution reactions, precipitation reaction occur only on the surface of the precursor (Ishikawa, 2010). In immersing the granule  $\text{CaSO}_4$  in  $\text{Na}_2\text{CO}_3$  solution as shown in the reactions below:

Solubility of  $\text{CaSO}_4$  is very low, but it can be partially dissolved in aqueous solution. Granule  $\text{CaSO}_4$  releases  $\text{Ca}^{2+}$  and  $\text{SO}_4^{2-}$  (reaction 1),  $\text{Ca}^{2+}$  reacts with  $\text{CO}_3^{2-}$  from a solution of  $\text{Na}_2\text{CO}_3$  will be saturated to  $\text{CaCO}_3$  because of calcite solubility is very small ( $K_{sp} = 10^{-8.4}$  at  $20^\circ\text{C}$ ). Calcite crystals are precipitated on the surface of the granule. The overall reaction can be seen in reaction 3,  $\text{Na}_2\text{SO}_4$  formed is by product which is produced by high solubility and dissolved in water. <sup>5</sup>

Immersion temperature and duration can have an effect on precipitation dissolution reactions (Noorzidah, 2016; Ishikawa et al., 2017) along with the results of 12-hour studies where pure  $\text{CaCO}_3$  not formed (figure 2). Crystals of  $\text{CaCO}_3$  can be formed by immersion treatment at  $100^\circ\text{C}$ , seen in the XRD characterization results that match with the ICDD

reference (no. 96-450-2444), 12-hour immersion produces crystals showing the presence of CaCO<sub>3</sub> phase formed at 2θ 30° (figure 3 ).

This study has its shortcomings, because the resulting CaCO<sub>3</sub> granule still contains the CaSO<sub>4</sub> phase. Further studies are needed regarding the effect of the long immersion of CaSO<sub>4</sub> in Na<sub>2</sub>CO<sub>3</sub> to produce pure CaCO<sub>3</sub>. The use of CaSO<sub>4</sub> as a precursor is a potential material in producing CaCO<sub>3</sub> within a shorter time. From the results of this study it can be concluded that the use of CaSO<sub>4</sub> granules to produce CaCO<sub>3</sub> granules can be done by soaking for 12 hours in a solution of 0.5 mol /L Na<sub>2</sub>CO<sub>3</sub> at 100°C. Longer immersion is expected to totally convert CaSO<sub>4</sub> to CaCO<sub>3</sub>.
